Fact sheets
The soybean plant has it all. It represents a true triumph like no other cultivated plant in human history. This is because it has a high amount of protein and it binds nitrogen. Soy is now used as a meat substitute around the world. Tofu and soy milk are popular and are now as much a part of a balanced and healthy diet as bread and butter. However, soy is mainly used as animal feed.

**Soy – the miracle plant**

**An efficient crop**

Soy is not only ecological, it is also one of the most efficient agricultural crops around. If we wanted to meet our protein needs with a different crop, we would have to plant a much larger area. And soy is very easy for farm animals to consume and digest.

**Soy is environmentally valuable**

Soy can meet about two-thirds of its nitrogen needs on its own. So it needs less fertilizer. It’s also ideally suited for crop rotation. Unlike corn, which results in a loss of topsoil, soy contributes to the enrichment of topsoil. So fields remain fertile, are better aerated and are easier to work.

**Usable Protein per Acre of Farmland**

**Soy can be used in many different ways**

The unique composition of and substances in the soy plant make it one of the most versatile agricultural crops in the world. It has a number of uses. Soy is used for food (about 5% of global production), for cosmetics and in the chemical industry (20%), and for animal feed (75%).

**Source:** Danube Soya
Swiss soy cultivation

With the exception of fodder, agricultural crops in Switzerland can only make a very limited contribution to domestic production of sources of protein. About 1,500 hectares of soy were planted in 2014. This resulted in a yield of 3,882 tons of soybeans. Of this, 2,000 tons (i.e., 0.8% of annual demand) was used for fodder.

Use as food

Some 75% of soy is used for animal feed. Because of its high protein content and favorable composition of essential amino acids soy is ideal for feeding pigs and poultry. The production of chickens and eggs requires the most soy. Chickens need a lot of protein. By nature, they like to eat worms and bugs. Cows, by contrast, prefer to eat mainly grass.

The soybean is unique

Like peas, beans and lentils, soybeans are legumes and they have the highest protein content in this group. Soy has a good fatty acid composition. It contains little saturated fat and a high proportion of polyunsaturated fat. Like other plant-based oils, soy oil contains no cholesterol. These two factors combined have a positive impact on fat metabolism. Soy beans are a good source of fiber. Consuming 50 grams of soybeans will provide you with a third of your daily fiber requirement. Soybeans also contain numerous other vitamins, such as vitamin B1, vitamin B2, folic acid and vitamin E. Soy is also rich in calcium and magnesium.
The global increase in the consumption of meat, eggs and milk products has led to an expansion of soybean production in North and South America. The prohibition against using animal protein as fodder, low production costs in the US, Brazil and Argentina, and genetically modified soy have made the soy plant one of the most important components in feeding our livestock. And this has had negative consequences for the environment and humanity.

A boom with consequences

Market forces shift to Asia

Soy is mainly produced in North and South America. The US, Brazil and Argentina account for 80% of total global production. China is now the largest importer of soy. Until 1990, it imported almost no soy. Europe and Asia’s addiction to protein is significant.

Hunger for soy remains unabated

Demand for and production of soy have increased fivefold over the past 40 years. The main reasons for this development are the pent-up demand for animal protein in Asia and the shift in meat consumption in developed countries toward low-fat poultry. Some 111 million hectares of land were planted with soybeans in 2014. This resulted in a harvest of 312 million tons.
Switzerland’s protein needs

Switzerland, too, depends on soy imports. The country only meets 14% of its crude protein needs on its own. It doesn’t have the varieties, yield stability or climatic and topographical conditions to be able to expand production of protein feed substantially. Switzerland therefore imported 285,000 tons of soybeans and soybean meal for animal feed in 2015, most of it from Brazil.

Europe’s importance grows

Brazil is the only major producer that offers GMO-free soy in large quantities. But the percentage of genetically-modified soy is constantly on the rise in Brazil. Wholesalers are refusing to buy soy produced on land in Brazil’s Amazon region that was cleared after July 2006. Today, some 5,000 square kilometers of forest are cut down each year. Ten years ago it was five times as much. Yet the pressure on Brazil’s Cerrado region, with its extraordinary biodiversity, remains unabated. About half of this region has been converted into farmland since the end of 1950.

Consequences for humanity and the environment

Soy is an important source of protein for people and animals and a crucial source of income and foreign currency for cultivating countries. Yet legumes also have negative consequences for the environment. These range from deforestation through water pollution to soil erosion and decreasing biodiversity. The increase in soy cultivation can also lead to social conflicts and tensions between producers and local populations based on land and worker rights.

GMO-free

According to estimates, 82% of global soy crops have been genetically modified. In the US and Brazil, 93% and 94%, respectively, of soy that is produced has been genetically modified. In Argentina, the figure is 100%. Switzerland has always chosen not to plant or import any genetically-modified soy.
In the global context, Switzerland is not a significant soy producer or consumer. Its share of global production is 0.001%, while it accounts for just 0.1% of worldwide consumption. Yet Switzerland is considered a trailblazer of more sustainable soy production. Swiss stakeholders like Coop and WWF were the first to recognize and deal with the issue of the global boom in soy. Together, they created the “Basel Criteria” in 2004, which seeks to encourage sustainable soy cultivation.

Exemplary industry solution

FROM THE “BASEL CRITERIA” TO THE SOY NETWORK SWITZERLAND

2004
In 2004, the WWF and Coop created the “Basel Criteria” to ensure sustainable soy cultivation and thus contribute to a substantial change in mindset in the soy industry. The Basel Criteria formed the basis for standards such as ProTerra and RTRS.

2006
Import of the first 1,000 tons of certified soy meal by fenaco. Challenges: Establishment of functioning certification organizations, credible and sustainable value added chain, achievement of critical mass.

2011
Foundation of the Soy Network Switzerland. Goal: Increase the percentage of responsible soy production to at least 90%.

2013
Switzerland was one of the first signatories of the Danube Soya Initiative to promote soy cultivation in Europe.

2015
In 2015, the share of imports of responsibly produced soy is 94%.

2016
Foundation of the Soy Network Switzerland with 19 founding organizations.

Sustainable standards are part of the solution

In order to achieve environmental and social improvements in the cultivation of soy in places like South America, minimum standards, such as ProTerra and RTRS, are an important step. Thanks to controls, the standards ensure compliance with the law. The common thread of these standards is that they ensure responsible soy production. ProTerra and RTRS meet the following (GMO-free) criteria:

- **Environmental criteria**
  - No clearing of old-growth forests and habitats rich in biodiversity.
  - Application of integrated production methods with the goal of reducing the use of potentially harmful pesticides and fertilizers.
  - Protection of soil and water.

- **Social criteria**
  - Observance of labor rights (minimum wages, no child labor, fair working conditions, worker protection).
  - Respect for traditional land rights.

- **GMO-free**
  - Farms and the flow of goods is monitored by independent agencies.
The commitment goes on
The import of responsibly produced soy meal is an opportunity to curtail the negative consequences of soy cultivation. But the members of the Soy Network are not stopping there. They are involved in research projects to develop alternative sources of protein. They are looking for alternative sources in Europe and promoting grassland-based milk and meat production.

Switzerland is a role model
The collaboration of key stakeholders from the Swiss agriculture and food industries is having an impact:

- **94%**
  Since 2011, the members of the Soy Network have increased the share of responsibly produced soy used as feed from about 40% to 94%.

- **Pesticides**
  The use of chemical agents such as endosulfan, paraquat and methamidophos has been reduced and banned in Brazil. Since 2016 Danube Soya prohibits the use of desiccants such as glyphosate.

- **Footprint**
  An environmental balance sheet prepared by Agroscope shows that the environmental footprint can be reduced through the use of European soy.

Cargill, ADM
Large agricultural companies, such as Cargill and ADM, now offer certified soy.

EU
Other countries, such as Holland, Belgium, Germany and Sweden have created initiatives and objectives similar to Switzerland’s.

Brazil
In Brazil, suppliers have adapted to the European demand for responsible, certified and GMO-free soy.

The outlook
The share of responsibly produced soy is only about 2% worldwide. Demand for sustainable soy for use as feed previously only came from Europe. Switzerland needs to maintain the high level of quality and help further develop international standards. The focal points are:

- Increase the share of European production of soy further.
- Promote the image of cultivated plants among the broader public.
- Measure, increase and document the positive impact locally for the environment and producers.
